Tropical Agriculture (IITA)

## Propagation of Banana and Plantain Disease-Cleaned Suckers

Propagate Success with Clean Suckers

Macro-propagation involves two techniques: field-based (decapitation) and detached corm (beds). It ensures disease-free seedlings, promoting uniform growth and stress resistance. Clean knives and hardened sprouts are vital for success.

Complete decapitation with excised meristem (top) and sprouting suckers (bottom)

- This technique reduces financial barriers by offering a low-cost method of obtaining diseasefree seedlings
- Macro-propagation ensures more uniform growth of banana and plantain seedlings.

## Key points to design your business plan

plantlets, negatively impacting their adaptation

and performance in the field.

The Propagation of Disease-Cleaned Suckers technology enhances banana and plantain production by providing disease-free planting materials, reducing losses from pests and diseases.

- Costs for propagation equipment and infrastructure are relatively low, with decapitation costing about 0.30 USD per 100 plantlets every four months and chamber construction around 2,300 USD.
- A study in South-Kivu DR Congo demonstrates the profitability of macro-propagation, yielding a net profit between 725 and 1,050 USD per cycle.
